

Blocking: An R Package for Blocking of Records for Record Linkage and Deduplication

by Maciej Beręsewicz and Adam Struzik

Abstract An abstract of less than 250 words.

1 Introduction

Interactive data graphics provides plots that allow users to interact them. One of the most basic types of interaction is through tooltips, where users are provided additional information about elements in the plot by moving the cursor over the plot.

This paper will first review some R packages on interactive graphics and their tooltip implementations. A new package [ToOoOITiPs](#) that provides customized tooltips for plot, is introduced. Some example plots will then be given to showcase how these tooltips help users to better read the graphics.

2 Background

Some packages on interactive graphics include [plotly](#) ([Sievert, 2020](#)) that interfaces with Javascript for web-based interactive graphics, [crosstalk](#) ([Cheng and Sievert, 2021](#)) that specializes cross-linking elements across individual graphics. The recent R Journal paper [tsibbletalk](#) ([Wang and Cook, 2021](#)) provides a good example of including interactive graphics into an article for the journal. It has both a set of linked plots, and also an animated gif example, illustrating linking between time series plots and feature summaries.

3 Blocking of records using blocking function

4 Integration with existing packages

5 Case study

5.1 Record linkage example

Let us first load the required packages.

```
library(blocking)
library(data.table)
```

We demonstrate the use of blocking function for record linkage on the foreigners dataset included in the package. This fictional representation of the foreign population in Poland was generated based on publicly available information, preserving the distributions from administrative registers. It contains 110,000 rows with 100,000 entities. Each row represents one record, with the following columns:

- fname – first name,
- sname – second name,
- surname – surname,
- date – date of birth,
- region – region (county),

- country – country,
- true_id – person ID.

```
data(foreigners)
head(foreigners)
```

```
#>      fname  sname      surname      date region country true_id
#>   <char> <char>    <char>    <char> <char>  <char>  <num>
#> 1:   emin          imanov 1998/02/05          031      0
#> 2:  nurlan      suleymanli 2000/08/01          031      1
#> 3:   amio      maharrsmov 1939/03/08          031      2
#> 4:   amik      maharramof 1939/03/08          031      2
#> 5:   amil      maharramov 1993/03/08          031      2
#> 6:  gadir      jahangirov 1991/08/29          031      3
```

We split the dataset into two separate files: one containing the first appearance of each entity in the foreigners dataset, and the other containing its subsequent appearances.

```
foreigners_1 <- foreigners[!duplicated(foreigners$true_id), ]
foreigners_2 <- foreigners[duplicated(foreigners$true_id), ]
```

Now in both datasets we remove slashes from the date column and create a new string column that concatenates the information from all columns (excluding true_id) in each row.

```
foreigners_1[, date := gsub("/", "", date)]
foreigners_1[, txt := paste0(fname, sname, surname, date, region, country)]
foreigners_2[, date := gsub("/", "", date)]
foreigners_2[, txt := paste0(fname, sname, surname, date, region, country)]
head(foreigners_1)
```

```
#>      fname  sname      surname      date region country true_id
#>   <char> <char>    <char>    <char> <char>  <char>  <num>
#> 1:   emin          imanov 19980205          031      0
#> 2:  nurlan      suleymanli 20000801          031      1
#> 3:   amio      maharrsmov 19390308          031      2
#> 4:  gadir      jahangirov 19910829          031      3
#> 5:   zaur      bayramova 19961006 01261    031      4
#> 6:   asif      mammadov 19970726          031      5
#>      txt
#>   <char>
#> 1:   eminimanov19980205031
#> 2:  nurlansuleymanli20000801031
#> 3:   amiomaharrsmov19390308031
#> 4:   gadirjahangirov19910829031
#> 5: zaurbayramova1996100601261031
#> 6:   asifmammadov19970726031
```

General use

We use the newly created columns in the blocking function, which relies on the default [rnn descent](#) (Nearest Neighbor Descent) algorithm based on cosine distance. Additionally, we set `verbose = 1` to monitor progress. Note that a default parameter of the blocking function is `seed = 2023`, which sets the random seed.

```
result_reclin <- blocking(x = foreigners_1$txt,
                          y = foreigners_2$txt,
                          verbose = 1)
```

```
#> ===== creating tokens =====
#> ===== starting search (nnd, x, y: 100000, 10000, t: 1232) =====
#> ===== creating graph =====
```

Now we examine the results of record linkage.

- We have created 6,469 blocks.
- The blocking process utilized 1,232 columns (2 character shingles).
- We have 3,916 blocks of 2 elements, 1,604 blocks of 3 elements,..., 2 blocks of 7 elements.

```
result_reclin
```

```
#> =====
#> Blocking based on the nnd method.
#> Number of blocks: 6469.
#> Number of columns used for blocking: 1232.
#> Reduction ratio: 0.9999.
#> =====
#> Distribution of the size of the blocks:
#>      2      3      4      5      6      7
#> 3916 1604  926   19      2      2
```

Structure of the object is as follows:

- `result` – a `data.table` with identifiers and block IDs,
- `method` – name of the ANN algorithm used,
- `deduplication` – whether deduplication was applied,
- `representation` – whether shingles or vectors were used,
- `metrics` – metrics for quality assessment (here `NULL`),
- `confusion` – confusion matrix (here `NULL`),
- `colnames` – column names used for the comparison,
- `graph` – an **igraph** object, mainly for visualization (here `NULL`).

```
str(result_reclin, 1)
```

```
#> List of 8
#> $ result      :Classes 'data.table' and 'data.frame': 10000 obs. of  4 variables:
#> ..- attr(*, ".internal.selfref")=<externalptr>
#> $ method      : chr "nnd"
#> $ deduplication : logi FALSE
#> $ representation: chr "shingles"
#> $ metrics      : NULL
#> $ confusion    : NULL
#> $ colnames     : chr [1:1232] "0a" "0b" "0c" "0m" ...
#> $ graph        : NULL
#> - attr(*, "class")= chr "blocking"
```

The resulting `data.table` has four columns:

- `x` – reference dataset (i.e. `foreigners_1`) – this may not contain all units of `foreigners_1`,
- `y` – query (each row of `foreigners_2`) – this may not contain all units of `foreigners_2`,
- `block` – block ID,
- `dist` – distance between objects.

```
head(result_reclin$result)
```

```
#>      x      y block      dist
#>   <int> <int> <num>   <num>
#> 1:      3      1      1 0.2216882
#> 2:      3      2      1 0.2122737
#> 3:     21      3      2 0.1172652
#> 4:     57      4      3 0.1863238
#> 5:     57      5      3 0.1379310
#> 6:     61      6      4 0.2307692
```

Let's examine the first pair. Obviously, there are typos in the fname and surname. Nevertheless, the pair is a match.

```
cbind(t(foreigners_1[3, 1:6]), t(foreigners_2[1, 1:6]))
```

```
#>      [,1]      [,2]
#> fname  "amio"    "amik"
#> sname   ""       ""
#> surname "maharrsmov" "maharramof"
#> date    "19390308"  "19390308"
#> region  ""         ""
#> country "031"      "031"
```

Now we use the `true_id` values to evaluate our approach.

```
matches <- merge(x = foreigners_1[, .(x = 1:N, true_id)],
                 y = foreigners_2[, .(y = 1:N, true_id)],
                 by = "true_id")
matches[, block := rleid(x)]
head(matches)
```

```
#> Key: <true_id>
#>   true_id      x      y block
#>   <num> <int> <int> <int>
#> 1:      2      3      1      1
#> 2:      2      3      2      1
#> 3:     20     21      3      2
#> 4:     56     57      4      3
#> 5:     56     57      5      3
#> 6:     60     61      6      4
```

We have 10,000 matched pairs. We use the `true_blocks` parameter in the blocking function to specify the true block assignments. We obtain the quality metrics for the assessment of record linkage.

```
result_2_reclin <- blocking(x = foreigners_1$txt,
                           y = foreigners_2$txt,
                           verbose = 1,
                           true_blocks = matches[, .(x, y, block)])
```

```
#> ===== creating tokens =====
#> ===== starting search (nnd, x, y: 100000, 10000, t: 1232) =====
#> ===== creating graph =====
```

```
result_2_reclin
```

```
#> =====
```

```
#> Blocking based on the nnd method.
#> Number of blocks: 6469.
#> Number of columns used for blocking: 1232.
#> Reduction ratio: 0.9999.
#> =====
#> Distribution of the size of the blocks:
#>   2   3   4   5   6   7
#> 3916 1604 926  19   2   2
#> =====
#> Evaluation metrics (standard):
#>      recall  precision      fpr      fnr  accuracy specificity
#>    96.7782    78.7000    0.0038    3.2218    99.9957    99.9962
#>    f1_score
#>    86.8079
```

For example, our approach results in a 3.22% false negative rate (FNR). To improve this, we can increase the epsilon parameter of the NND method from 0.1 to 0.5. To do so, we configure the `control_ann` parameter in the blocking function using the `controls_ann` and `control_nnd` functions.

```
result_3_reclin <- blocking(x = foreigners_1$txt,
                           y = foreigners_2$txt,
                           verbose = 1,
                           true_blocks = matches[, .(x, y, block)],
                           control_ann = controls_ann(
                             nnd = control_nnd(epsilon = 0.5)))

#> ===== creating tokens =====
#> ===== starting search (nnd, x, y: 100000, 10000, t: 1232) =====
#> ===== creating graph =====

result_3_reclin

#> =====
#> Blocking based on the nnd method.
#> Number of blocks: 6392.
#> Number of columns used for blocking: 1232.
#> Reduction ratio: 0.9999.
#> =====
#> Distribution of the size of the blocks:
#>   2   3   4   5   7
#> 3798 1613 956  21   4
#> =====
#> Evaluation metrics (standard):
#>      recall  precision      fpr      fnr  accuracy specificity
#>    96.8682    80.1100    0.0036    3.1318    99.9960    99.9964
#>    f1_score
#>    87.6957
```

That decreases the FNR to 3.13%.

Integration with the [reclin2](#) package

Let us load the [reclin2](#) package.

```
library(reclin2)
```

Now we present record linkage using the `pair_ann` function. It is based on the `pair_minim` function and reuses some of its source code. The `on` parameter specifies the column names for the approximate nearest neighbours (ANN) search. Setting `deduplication = FALSE` enables record linkage. The function works as follows.

```
result_pair_ann <- pair_ann(x = foreigners_1,
                           y = foreigners_2,
                           on = c("fname", "sname", "surname",
                                "date", "region", "country"),
                           deduplication = FALSE)

head(result_pair_ann)

#> First data set: 100 000 records
#> Second data set: 10 000 records
#> Total number of pairs: 6 pairs
#> Blocking on: 'fname', 'sname', 'surname', 'date', 'region', 'country'
#>
#>      .x      .y block
#>   <int> <int> <num>
#> 1:      3      1      1
#> 2:      3      2      1
#> 3:     21      3      2
#> 4:     57      4      3
#> 5:     57      5      3
#> 6:     61      6      4
```

The `pair_ann` function returns the total number of pairs. This output can be integrated into the pipeline of the [reclin2](#) package. We compare pairs across all selected variables using the Jaro-Winkler distance. The similarity scores are summed across the variables and we set `threshold = 4.5` to accept a pair.

```
selected_pair_ann <- result_pair_ann |>
  compare_pairs(on = c("fname", "sname", "surname",
                      "date", "region", "country"),
               comparators = list(cmp_jarowinkler())) |>
  score_simple("score",
              on = c("fname", "sname", "surname",
                    "date", "region", "country")) |>
  select_threshold("threshold", score = "score", threshold = 4.5) |>
  link(selection = "threshold")

head(selected_pair_ann)

#> Total number of pairs: 6 pairs
#>
#> Key: <.y>
#>      .y      .x  fname.x sname.x surname.x date.x region.x country.x

```

We observe that the example pairs are matches.

5.2 Deduplication example

We demonstrate deduplication using the blocking function on the `RLdata500` dataset from the [RecordLinkage](#) package. Note that the dataset is included in the blocking package. It contains artificial personal data. Fifty records have been duplicated with randomly generated errors. Each row represents one record, with the following columns:

- `fname_c1` – first name, first component,
- `fname_c2` – first name, second component,
- `lname_c1` – last name, first component,
- `lname_c2` – last name, second component,
- `by` – year of birth,
- `bm` – month of birth,
- `bd` – day of birth,
- `rec_id` – record id,
- `ent_id` – entity id.

```
data(RLdata500)
head(RLdata500)
```

```
#>      fname_c1 fname_c2 lname_c1 lname_c2      by      bm      bd rec_id ent_id
#>      <char>  <char>    <char>    <char> <int> <int> <int> <int> <int>
#> 1:    CARSTEN      MEIER      1949      7     22      1     34
#> 2:      GERD      BAUER      1968      7     27      2     51
#> 3:    ROBERT    HARTMANN      1930      4     30      3    115
#> 4:    STEFAN      WOLFF      1957      9      2      4    189
#> 5:      RALF    KRUEGER      1966      1     13      5     72
#> 6:    JUERGEN    FRANKE      1929      7      4      6    142
```

We create a new column (`id_count`) that indicates how many times a given unit occurs and then add leading zeros to the `bm` and `bd` columns. Finally, we create a new string column that concatenates the information from all columns (excluding `rec_id`, `ent_id` and `id_count`) in each row.

```
RLdata500[, id_count := .N, ent_id]
RLdata500[, bm:=sprintf("%02d", bm)]
RLdata500[, bd:=sprintf("%02d", bd)]
RLdata500[, txt:=tolower(
  paste0(fname_c1,fname_c2,lname_c1,lname_c2,by,bm,bd))]
head(RLdata500)
```

```

#>   fname_c1 fname_c2 lname_c1 lname_c2   by   bm   bd rec_id ent_id
#>   <char>  <char>  <char>  <char> <int> <char> <char> <int> <int>
#> 1:  CARSTEN          MEIER      1949   07   22     1     34
#> 2:    GERD          BAUER      1968   07   27     2     51
#> 3:  ROBERT      HARTMANN      1930   04   30     3    115
#> 4:  STEFAN          WOLFF      1957   09   02     4    189
#> 5:    RALF      KRUEGER      1966   01   13     5     72
#> 6: JUERGEN          FRANKE      1929   07   04     6    142
#>   id_count          txt
#>   <int>          <char>
#> 1:      1 carstenmeier19490722
#> 2:      2  gerdbauer19680727

#> 6:      1 juergenfranke19290704

```

As in the previous example, we use the txt column in the blocking function. This time, we set `ann = hnsw` to use the Hierarchical Navigable Small World (HNSW) algorithm from the **RcppHNSW** package and `graph = TRUE` to obtain an **igraph** object for visualization.

```

result_dedup_hnsw <- blocking(x = RLdata500$txt,
                             ann = "hnsw",
                             graph = TRUE,
                             verbose = 1)

#> ===== creating tokens =====
#> ===== starting search (hnsw, x, y: 500, 500, t: 429) =====
#> ===== creating graph =====

```

The results are as follows.

```

result_dedup_hnsw

#> =====
#> Blocking based on the hnsw method.
#> Number of blocks: 133.
#> Number of columns used for blocking: 429.
#> Reduction ratio: 0.9916.
#> =====
#> Distribution of the size of the blocks:
#>  2  3  4  5  6  7  8  9 10 11 12 17
#> 46 35 23  8  6  6  2  3  1  1  1  1

head(result_dedup_hnsw$result)

#>      x      y block      dist
#>   <int> <int> <num>   <num>
#> 1:    1    64    35 0.47379863
#> 2:    2    43     1 0.08074522
#> 3:    2   486     1 0.41023219
#> 4:    3   450    88 0.43263358
#> 5:    4    50    13 0.52565831
#> 6:    5   128     2 0.51333570

```

Now we visualize connections using the obtained graph.

```
plot(result_dedup_hnsw$graph, vertex.size = 1, vertex.label = NA)
```

Figure 1: Connection graph

We create a long data.table with information on blocks and units from the original dataset.

```
df_block_melted <- melt(result_dedup_hnsw$result, id.vars = c("block", "dist"))
df_block_melted_rec_block <- unique(df_block_melted[, .(rec_id=value, block)])
head(df_block_melted_rec_block)
```

```
#>   rec_id block
#>   <int> <num>
#> 1:     1    35
#> 2:     2     1
#> 3:     3    88
#> 4:     4    13
#> 5:     5     2
#> 6:     6    35
```

We add the block information to the final dataset.

```
RLdata500[df_block_melted_rec_block, on = "rec_id", block_id := i.block]
head(RLdata500)
```

```
#>   fname_c1 fname_c2 lname_c1 lname_c2   by   bm   bd rec_id ent_id
#>   <char>   <char>   <char>   <char> <int> <char> <char> <int> <int>
#> 1:  CARSTEN                MEIER    1949   07   22     1    34
```

```

#> 2:   GERD           BAUER           1968   07   27   2   51
#> 3:  ROBERT       HARTMANN        1930   04   30   3  115
#> 4:  STEFAN       WOLFF           1957   09   02   4  189
#> 5:   RALF       KRUEGER          1966   01   13   5   72
#> 6: JUERGEN       FRANKE           1929   07   04   6  142
#>   id_count          txt block_id
#>      <int>          <char>   <num>
#> 1:      1 carstenmeier19490722    35
#> 2:      2   gerdbauer19680727     1
#> 3:      1 roberthartmann19300430    88
#> 4:      1  stefanwolff19570902    13
#> 5:      1  ralfkrueger19660113     2
#> 6:      1 juergenfranke19290704    35

```

We can check in how many blocks the same entities (`ent_id`) are observed. In our example, all the same entities are in the same blocks.

```
RLdata500[, .(uniq_blocks = uniqueN(block_id)), .(ent_id)][, .N, uniq_blocks]
```

```

#>   uniq_blocks    N
#>      <int> <int>
#> 1:         1  450

```

Now we can visualize the distances between the units stored in the `result_dedup_hnsw$result` dataset. Clearly we have a mixture of two groups: matches (close to 0) and non-matches (close to 1).

```

hist(result_dedup_hnsw$result$dist, xlab = "Distances",
      ylab = "Frequency", breaks = "fd",
      main = "Distances calculated between units")

```

Distances calculated between units

Figure 2: Distances calculated between units

Finally, we visualize the result based on the information whether a block contains matches or not.

```
df_for_density <- copy(df_block_melted[block %in% RLdata500$block_id])
df_for_density[, match:= block %in% RLdata500[id_count == 2]$block_id]

plot(density(df_for_density[match==FALSE]$dist),
     col = "blue", xlim = c(0, 0.8),
     main = "Distribution of distances between\n
clusters type (match=red, non-match=blue)")
lines(density(df_for_density[match==TRUE]$dist),
     col = "red", xlim = c(0, 0.8))
```

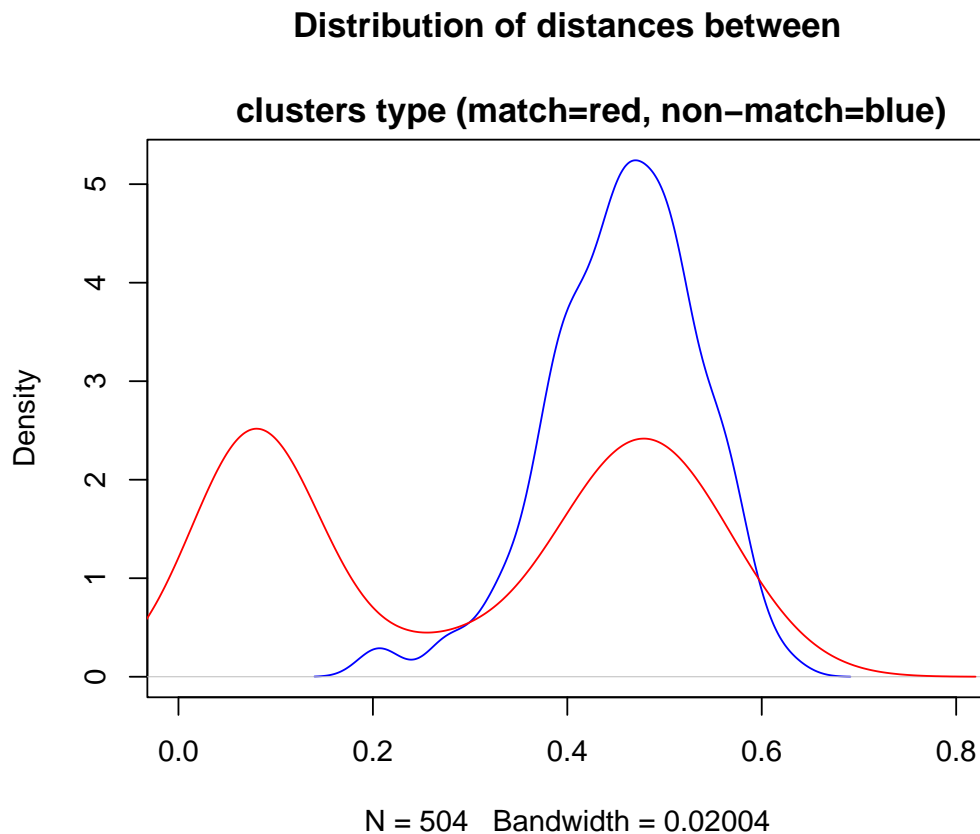

Figure 3: Distribution of distances between clusters type

Now we compare the evaluation metrics across all ANN algorithms supported by the blocking function, i.e. NND, HNSW, Approximate Nearest Neighbors Oh Yeah (Annoy, from the [RcppAnnoy](#) package), Locality-sensitive hashing (LSH, from the [mlpack](#) package), and k-Nearest Neighbors (kNN – denoted as "kd", from the [mlpack](#) package). We use the `rec_id` and `ent_id` columns from the `RLdata500` dataset to specify the true blocks and then calculate evaluation metrics for all algorithms. Additionally, we assess blocking using the `klsh` function from the [klsh](#) package, configured to create 10 blocks and 100 blocks, respectively. In both settings, we use 20 random projections and 2-character shingles. The results are as follows (`klsh_10` and `klsh_100` refer to the `klsh` algorithm with 10 blocks and 100 blocks, respectively).

```
true_blocks <- RLdata500[, c("rec_id", "ent_id"), with = FALSE]
setnames(true_blocks, old = c("rec_id", "ent_id"), c("x", "block"))
eval_metrics <- list()
ann <- c("nnd", "hns", "annoy", "lsh", "kd")
for (algorithm in ann) {
  eval_metrics[[algorithm]] <- blocking(x = RLdata500$txt,
                                       ann = algorithm,
                                       true_blocks = true_blocks)$metrics
}

set.seed(2025)
blocks_klsh_10 <- klsh::klsh(
  r.set = RLdata500[, c("fname_c1", "fname_c2", "lname_c1",
                        "lname_c2", "by", "bm", "bd")],
  p = 20,
  num.blocks = 10,
```

6 Customizing tooltip design with ToOoOLTiPs

ToOoOLTiPs is a packages for customizing tooltips in interactive graphics, it features these possibilities.

7 A gallery of tooltips examples

The [palmerpenguins](#) data ([Horst et al., 2020](#)) features three penguin species which has a lovely illustration by Alison Horst in [Figure 4](#).

Table 1 prints at the first few rows of the penguins data:

Figure 5 shows an plot of the penguins data, made using the [ggplot2](#) package.

```
penguins %>%
```

Figure 4: Artwork by allison_horst

```
ggplot(aes(x = bill_depth_mm, y = bill_length_mm,
           color = species)) +
  geom_point()
```

8 Summary

We have displayed various tooltips that are available in the package **ToOoOiTiPs**.
